Box Patent Application
Assistant Commissioner for Patents
Washington, D.C. 20231

REQUEST FOR CONTINUATION OF AN INTERNATIONAL APPLICATION
UNDER 37 C.F.R. §1.53(b)

This is a request for filing a continuation application under 37 C.F.R. §1.53(b) of prior pending international application number PCT/FI99/00334 filed on 23 April 1999 entitled TRANSMISSION ANTENNA DIVERSITY, which designated the United States.

1. ☒ Enclosed is a patent application containing 25 pages of specification, 14 pages of claims and 11 sheet(s) of drawings.
2. ☒ A preliminary amendment is enclosed.
3. ☒ Please amend the specification by inserting the following paragraph after the title:

This application is a continuation of international application serial number PCT/FI99/00334, filed 23 April 1999.

4. ☐ Small entity status
 - a. ☐ A small entity statement is enclosed.
 - b. ☐ A small entity statement was filed in the prior non provisional application.
 - c. ☐ is no longer claimed.

The filing fee is calculated below

CLAIMS				
	Number Filed	Number Extra	Rate	Fee
Total Claims	65	45	X \$18.00	\$ 252.00
Indep. Claims	10	7	X \$78.00	\$ 546.00
Multiply Dependent Claims				\$
			Basic Fee	\$ 690.00
			TOTAL	\$ 1488.00

5. ☒ Payment of filing fees
☐ A check in the amount of _____ is enclosed.
☐ Please charge Deposit Account Number 50-1038.
☒ Is deferred.
6. ☒ The Commissioner is hereby authorized to credit any overpayment or charge any fees required under 37 C.F.R. §1.16-1.18 to Deposit Account Number 50-1038.
7. ☒ The priority of Finnish application numbers 980915, filed 24 April 1998, and 981377, filed 12 June 1998, is claimed under 35 U.S.C. §119.
☐ A certified copy of the priority application is enclosed.
8. ☒ An unsigned Declaration is enclosed.
9. ☐ An assignment of the invention to _____, Recordation Form Cover Sheet (Patents Only) and a check in the amount of \$40.
10. ☒ An Information Disclosure Statement, Form PTO 1449 and copies of 4 citations are enclosed.

Transmission antenna diversity

Field of the invention

The invention concerns a method and an arrangement for arranging transmission antenna diversity in a mobile communication system.

Background of the invention

In radio systems implemented by CDMA (Code Division Multiple Access), the operation is based on scattered spectrum communication. The transmitted signal is scattered by an individual hash code W_i , e.g. a Walsh code, addressed to the subscriber, whereby the transmission is spread out on a broadband radio channel, which is e.g. 1,25; 6,4 or 20 MHz. Hereby it is possible on the same broadband radio channel to transmit simultaneously to several subscribers CDMA signals processed with different hash codes. In CDMA systems, the special hash code of each subscriber hereby produces a traffic channel in the system in the same sense as the time slot in a TDMA system. E.g. in an IS-95, the hash code means a code, by which the channels are distinguished from one another. All transmitted hash codes can also be multiplied by a scrambling code which is specific for the base transceiver station or the antenna. At the receiving end, the CDMA signal is broken up using the subscriber's hash code, whereby a narrow-band signal will result. The broadband signals of other subscribers represent noise in the receiver beside the desired signal. In this application reference is mostly made to a CDMA system in accordance with the IS-95 standard, although the invention is suitable for any system. In CDMA systems, the communication may be TDD-based (Time Division Duplex), whereby the uplink and downlink directions of the base station connections are set up at the same frequency in different time slots, or FDD-based (Frequency Division Duplex), whereby the frequencies of the uplink and downlink channels differ from each other by a duplex frequency.

It must be possible in all cellular systems to regulate at least the transmission power of the mobile station, so that its transmission will arrive at the base transceiver station with an adequate signal-to-noise ratio irrespectively of how far the mobile station is located from the base transceiver station. Power control is described in the following using a CDMA system as an example. Figure 1 in the appended drawing shows a downlink CDMA traffic

channel (Forward Traffic Channel), which includes the following code channels: a common channel, one synchronising channel, from one to seven calling channels and a maximum number of 61 traffic channels. The maximum is when there is only one calling channel besides the synchronising channel. Each code channel is orthogonally spread and thus broadened by using a random noise sequence phase quadrature pair .

On the common channel a scattered spectrum signal is transmitted constantly at standard power, which signal is used for synchronising the MS mobile stations and for other broadcasting to the mobile stations.

The traffic is used for transfer of user and signalling information to the mobile station MS. Each downlink traffic channel contains a power control sub-channel, on which power control commands are transferred to the mobile station during the connection, in response to which the mobile station will change its transmission power.

The power control sub-channel is formed so that power control bits are constantly transmitted among the bits of the normal traffic channel. The bits are located in the frame so that from the completed traffic channel, which is a convolution coded and interleaved frame formed by modulation symbols, two successive modulation symbols are removed at regular intervals and they are replaced by power control bits. The procedure is generally known in the field and it is called symbol puncturing. The puncturing pattern shows which symbols are removed from the frame and replaced with power control bits.

Figure 2 of the appended drawing shows signal transmission from the sender to the receiver in a telecommunications system. The information to be transmitted is conveyed over a transmission channel, such as a radio channel, modulated in a form suitable for the channel. Non-idealities of the transmission channel, such as signal reflections, noise and interference caused by other connections, will cause changes in the signal containing the information, so the signal perceived by the receiver is never an exact copy of the signal transmitted by the sender. By using channel coding the information transmitted in digital systems can be made to tolerate better any non-idealities of the transmission path. At the receiving end, the receiver corrects the received signal in a channel corrector based on a channel estimate, that is, with the aid of the channel characteristics known to itself, and it undoes the modulation and channel coding used on the transmission channel.

The mobile station MS is usually connected to a base station providing the best signal quality. For the duration of a handover during the call the mobile station may in CDMA systems be simultaneously connected to several base stations BS, until some base station signal turns out to be better than the others, whereby the call is continued through this base station BS. A handover of this kind is called soft handover.

In a mobile communications system environment, the reliable transmission is disturbed by signal fading on the radio path. To compensate for fading, various means have been developed in mobile communications systems, such as reception diversity and power control as well as some solutions based on diversity use of the transmission antenna. The published patent application EP-741 465 presents one such transmission diversity solution for implementation at the base station. In the publication, the mobile station chooses the best signal out of several transmission antenna signals and notifies the base station of this choice, whereupon the base station continues the transmission through this chosen antenna. The base station adds a first packet identifier to the first data packet and transmits the first data packet together with its identifier through one antenna. Correspondingly, the base station adds the second packet identifier to the second data packet and sends the second data packet together with its identifier through another antenna. The mobile station receives both these transmissions and compares the received signal levels with one another. Having chosen the optimum transmission branch, the mobile station notifies the base station of the chosen packet identifier in a control time slot. The base station sends the transmission intended for the concerned mobile station by way of the indicated antenna. According to the publication, the signals of several signal connections are combined in the coding stage before the transmission is directed to different transmission branches, so when using the antenna diversity according to the publication, all user data is sent through the same chosen transmission antenna branch. The method according to the publication is suitable for use also when the transmission and reception frequencies are different, that is, when frequency-division duplexing FDD is used.

It is a problem with known transmission antenna diversity methods and with the solution of the EP publication described above that the choice of antenna is centralised jointly for all subscriber connections, whereby all traffic is directed for transmission by way of one antenna. Thus, the solution of the

EP publication is not suitable for setting up several simultaneous subscriber connections by way of different antennas. It is another problem that the antenna chosen by a mobile station may be misinterpreted at the base station, when the choice notification is based on information of one bit or a few bits in the individual message. Due to data transmission errors, this information may be erroneous in the reception. If the base station misinterprets the antenna chosen by the mobile station and then transmits by way of the misinterpreted antenna, the data transmission quality will suffer from the base station to the mobile station, as the mobile station assumes that the transmission comes from the antenna it has chosen. The waiting value of the false interpretation in the information may hereby be up to 0.5. If the choice of antenna is misinterpreted at the base station, then e.g. the interpretation of power control bits may fail in the downlink direction. A further problem with the EP publication described above is that channels set up through different antennas are not orthogonal in relation to one another, whereby they will cause interference to each other.

Brief summary of the invention

The purpose of this invention is an individual choice of transmission diversity antenna for each receiving unit and to ensure the quality of data transmission through a reliable transmission antenna diversity.

These objectives are achieved through methods according to the invention, which are characterised in that which is said in the independent claims 1, 27, 28, 43 and 44. Advantageous embodiments of the invention are presented in the dependent claims.

The invention also aims at an arrangement for implementing transmission antenna diversity characterised in that which is said in the independent claims 55, 59 and 60.

The invention is based on the idea that the receiving unit chooses an optimum transmission antenna route for the transmitting unit, such as a transmission antenna branch or a transmission antenna beam, based on information produced for the broadcasting transmitted by the transmitting unit through each transmission antenna route or for the traffic channel transmission, and it announces its choice to the transmitting unit, which will connect the transmission to one transmission antenna route based on this received notification, independently of other subscriber connections.

In a preferred embodiment of the invention, the information is produced for the broadcasting in such a way that the broadcasting of the transmission antenna route of each transmitting unit is shaped in such a signal shaping manner individual for each antenna route, which identifies the antenna routes. Such individual signal shaping methods are e.g. an antenna route specific hash code, a hash code in parallel once or several times, a symbol pattern, a frequency offset or channel coding.

In another embodiment of the invention, the information for the broadcasting is produced in such a way that on the traffic channel of each transmission antenna route an individual emission is transmitted, which identifies the transmission antenna route. It is advantageous that the transmitting unit transmits user data through a transmission antenna route in accordance with a message which it receives hereafter, so that the receiving unit is able to verify the antenna route to be used for the transmission. In time division systems it is also possible that the individual emission is the same on all branches, but their transmission time slot is different. Hereby the combination of transmission time slot and identifier will determine the transmission antenna route.

It is an advantage of this kind of transmission antenna diversity that the quality of the data transmission will improve owing to the choice of an individual transmission antenna route. In addition, it is an advantage of the transmission antenna diversity according to the invention that it is possible therein independently to connect simultaneous subscriber connections through some transmission antenna route chosen in accordance with the invention, independently of the transmission antenna routes of other subscriber connections.

One embodiment of the invention achieves both a reliable message giving the antenna route choice information and a simple identification of the antenna route to be used for the transmission, whereby the receiving unit will always be aware of the transmission antenna route which is to be used for the transmission. Some embodiments of the invention have the advantage that they need less hash codes for spreading the transmission than in known transmission diversity solutions, when every antenna route does not need its own hash code.

List of figures

The invention will now be described more closely in connection with preferable embodiments and referring to the examples shown in Figures 3 - 11 of the appended drawings, wherein:

35

5 In the following, the invention will be described more closely in the light of a preferable embodiment of the invention and referring to Figures 3a and 3b. Figures 3a and 3b show by way of example a radio communication between only one base station BS and only one mobile station MS.

In the example shown in Figure 3a there are three transmission antennas ANT1 - ANT3 at base station BS, which antennas are located at a sufficient distance from each other. It is advantageous to locate the transmission antennas at a mutual distance of 10 - 20 wave lengths at the base station, so that by transmission diversity a difference is achieved in the route travelled by the signal and, on the other hand, so that the delay between the different signal routes would not become too long. The base station transmits through each transmission antenna ANT1 - ANT3 on a common channel a broadcast signal intended for all mobile stations, but individually shaped for each antenna branch. The mobile station MS receives the common transmission of all antennas ANT1 - ANT3 and of these received signals it determines which one is best, e.g. based on the signal level, the SIR (Signal to Interference Ratio) or the distance attenuation.

Figure 3c shows a corresponding antenna choice process in the case of two mobile stations MS1 and MS2. Both mobile stations MS1 and MS2 receive the broadcast signal of all transmission antenna branches of the base station BS. Each broadcast signal is shaped by a antenna branch specific method of signal shaping. Based on the broadcast signals, each mobile station MS1 and MS2 chooses the optimum transmission antenna branch for itself and notifies the base station BS of its choice. In the example shown in Figure 3d, base station BS continues the communication with mo-

mobile station MS1 through transmission antenna ANT2 and with mobile station MS2 through transmission antenna ANT3.

It is advantageous to have base station BS on the traffic channel also transmit an identifier identifying the antenna branch to be used for the transmission or to shape the user data to be transmitted on the traffic channel in accordance with the signal shaping method of the antenna branch to be used for the transmission, whereby mobile station MS is able to verify the antenna branch to be used for the transmission. Hereby mobile station MS identifies, which antenna branch is actually used for the transmission at the base station. The transmission antenna branch used by base station BS may be the same or a different antenna branch than the one chosen by the mobile station as the best antenna branch, depending on how successfully the antenna choice message relayed by the mobile station is interpreted at the base station. With the aid of the emission identifying the antenna branch to be relayed on the traffic channel, mobile station MS, however, is able in accordance with the present invention to check and identify the transmission antenna branch connected for use in the connection.

Figures 4a and 4b show detailed examples of implementations of the transmission of a common channel in accordance with the present invention for transmission through the antennas of all base stations, as is shown in Figure 3a described above. The example in Figure 4a shows those parts of the structure of the transmitting unit which are essential to the invention, e.g. of the transmitter unit at base station BS. The signal to be transmitted may be coded in coder 41 and then the coded signal may be interleaved in interleaving unit 42. The functionality of units 41 and 42 is not necessarily needed, if coding and interleaving of the transmission of the common channel is not desirable, so of these units one or both may be left out. In accordance with the invention. The signal is divided at the S/P unit 43 (serial to parallel) to all transmission antenna branches, in the example shown in Figure 4a to antenna branches 44 - 46. In the following, the structure of antenna branches will be described with the aid of antenna branch 44. In the antenna branch leading to antenna ANT1, the signal is scattered, spread and modulated in unit 47. In the example shown in Figure 4a, scattering is performed in accordance with the invention in all antenna branches using the same hash code W_0 , however, so that the scattering result of the different antenna branches is different at the symbol level. In unit 47 a sym-

ing and modulation in antenna branches 44 - 46. In unit 49 of antenna branch 44, the signal is scattered by hash code W_1 , which is an individual hash code for each antenna branch. In antenna branch 45, the scattering is correspondingly performed with hash code W_2 and in antenna branch 46 with hash code W_3 . The different hash codes are preferably mutually orthogonal. The receiving unit identifies the signals transmitted from the different antennas by the hash code W_i used in their scattering. Hereby the signal shaping method according to the invention which is established for the antenna branch is an individual hash code for each transmission antenna branch which identifies each antenna branch.

In addition to the examples shown above, the signal shaping method which identifies the antenna and which is to be arranged for the common channel may be a different frequency offset value to be established in the signal processing in the different antenna branches, or different channel coding, such as CRC (Cyclic Redundancy Check), block coding or convolution coding, or the same hash code used in signal scattering in the different antenna branches may be modulated in parallel one time or many times so that hash codes of different lengths are modulated in each antenna branch, e.g. hash code W_0 , in one antenna branch, with hash codes W_0W_0 and W_0-W_0 , in parallel in another antenna branch, and so on. The signal shaping method to be established for the antenna branch may also be a combination of the shaping methods mentioned above. The signal shaping method established for each transmission antenna branch is preferably orthogonal compared with the signal shaping methods of the other antenna branches, e.g. orthogonal hash codes or symbol patterns.

Figure 5a shows the structure of a transmitting unit in accordance with the invention as regards the traffic channel transmission. On the traffic channel, the user data is coded in coder 51 and it is interleaved in unit 52. In unit 53 the signal is scattered by hash code W , it is spread and modulated. The operation of unit 53 may be controlled based on an interpretation of an antenna choice message received from the mobile station, so that owing to the signal shaping method according to the invention which is individual for the transmission antenna branch, an identifier identifying the transmission antenna branch is formed on the traffic channel. Such a signal shaping method established for the antenna branch may be e.g. a symbol pattern as described above in connection with the common channel transmission, a

hash code, a hash code in parallel once or several times, a frequency offset, channel coding or a combination of those mentioned above. Switch 54 switches to the transmission antenna the shaped signal to be transmitted, based on an interpretation 59 of the received antenna choice message. The functionality of switch 54 may also be implemented by some known state-of-the-art switching arrangement. The signal is converted from baseband to radio frequency in RF unit 48 of the connected antenna branch 44, 45 or 46. The shaped user data signal is transmitted onto the radio path through the antenna of the connected antenna branch. The signals of the other subscriber connections are combined to the transmission antennas before the conversion in RF unit 48.

Figure 5b shows by way of example a combination of the signals of traffic channels TCH1 - TCH3 of three subscriber connections before the transmission to the radio path. The signal of traffic channel TCH1 is scattered by hash code W1 and spread out, using the switch SWITCH1. The shaped signal of traffic channel TCH1 is connected to the transmission antenna based on an interpretation CONTROL1 of the received antenna choice message. Correspondingly, the same procedure is used as regards the other traffic channels TCH2 and TCH3. The signals of different traffic channels to be connected to the same antenna are combined with each other after the traffic channel specific switches before the RF conversion. When desired, the traffic channel signal may be shaped in accordance with the interpretation of the antenna choice method by a signal shaping method which is individual for the antenna branch before switching of the switch SWITCH1-3.

In accordance with the above description, an antenna branch specific identifier may be added to the signal to be sent on the traffic channel, or the signal to be transmitted may be shaped in accordance with the invention by a transmission antenna specific signal shaping method, so that the mobile station will be able to identify from which antenna branch the transmission has taken place. Thus, signal shaping methods specific to the antenna branches are e.g. the above-mentioned different hash codes, the same hash code with different symbol patterns, a different frequency offset, a different channel coding and/or a different number of the same hash code in parallel. The signal shaping method to be established for the different antenna branches is preferably orthogonal compared with the signal shaping methods of the other antenna branches.

5

15

20

25

30

35

of the art notifies the mobile station MS on a control channel, e.g. on a call channel, of the hash code to be used in the data transmission. During the connection this hash code preferably remains the same, even if the transmission antenna were to be changed during the communication. The symbol pattern identifying the antenna may be located in a suitable place on the common channel and on the traffic channel. Correspondingly, in the channels shown in Figure 6 the other signal shaping methods mentioned above as examples are located along with the data bits shaped by them as well as the identifiers identifying the antenna branch.

Figure 7a shows a comparison of transmission antenna branches in the light of block diagrams of a transmitting unit 700 and a receiving unit 701. The figure shows only those parts of the units 700 and 701 which are essential for the comparison and choice of the broadcast and transmission antenna branches. The structure of the transmitting unit 700 is similar to the structure described in connection with the example shown in Figure 4a for shaping the common channel signal with antenna branch specific symbol patterns. From all antennas ANT1 - ANT3 a common channel signal is transmitted shaped by the individual symbol pattern of each antenna. In the receiving unit, these three signals are received through antenna 710 and in receiver 711 the signal is converted for baseband frequency. In decoder 712 the signal is demodulated and the spreading and scattering of the signal are undone. The broadcast data is conducted for further processing elsewhere in the receiving unit. A channel estimate for each signal is also formed in the decoder. Detector 713 compares the received signals with one another, e.g. the signal level, the signal-to-interference ratio SIR or the distance attenuation, and it detects the individual signal shaping method of each signal. The signal shaping method is detected before decoding. The antenna choosing unit 714 chooses an antenna branch suitable for the transmission based on the comparisons performed by detector 713, e.g. that antenna branch which produces the best signal level. The antenna choosing unit 714 transmits the signal shaping method of the chosen antenna branch to coder 715, which adds this emission to the other coded data which is intended for transmission to unit 700, either before or after coding. The information to be transmitted to the transmitting unit 700 is shaped in transmitter unit 716 into the form required on the radio path and it is transmitted by way of antenna 717 onto the radio path in a state-of-the-art manner.

Figure 7b shows a connection of an antenna branch to a traffic channel transmission in accordance with the invention in the light of block diagrams of a transmitting unit 700 and a receiving unit 701. The figure shows only those parts of units 700 and 701 which are essential for this functionality. The antenna 717 of the receiving unit 701 thus in the manner described in connection with Figure 7a transmits an emission stating the signal shaping method of the chosen antenna branch along with the other transmission intended for the transmitting unit 700. The antenna 750 of the transmitting unit 700 receives this signal and leads it to the receiver 751 for conversion. The antenna 750 may also be one of the antennas ANT1 - ANT3. In receiver 751 the baseband-converted signal is led to decoder 752, which demodulates, undoes the spreading and scattering of the signal in a state-of-the-art manner and separates the antenna choice message from the other data. The received emission of the signal shaping method of the antenna branch is led by route 59 to control the connecting to the antenna branch used for the transmission of the user data to be transmitted from transmitting unit 700 to receiving unit 701 and possibly to control the addition of the antenna branch specific identifier to the user data or the shaping of the user data. As regards the transmission side of the traffic channel, the structure of unit 700 is similar to the structure described in connection with Figure 5a, whereby the coded and interleaved user data is scattered by the hash code reserved for the connection and it is spread out and modulated. In addition, the user data may be shaped with the signal shaping method established for the antenna branch connected for the transmission or an antenna branch specific identifier may be added to the user data. Signal shaping methods are e.g. antenna branch specific hash codes, symbol patterns, the use of a hash code in parallel once or several times, channel coding and/or frequency offset. The antenna to be used for the transmission is determined by the control 59, which controls switch 54 to switch to the transmitting antenna the shaped signal to be transmitted, in the example shown in Figure 7b to antenna ANT2. The RF unit 48 of the antenna branch of antenna ANT2 converts the signal to be transmitted from baseband to radio frequency in a state-of-the-art manner.

The traffic channel user data transmitted through antenna ANT2 is received through antenna 710 of the receiving unit 701 and it is led after the conversion in receiver 711 to decoder 712, which demodulates, undoes the

signal spreading and scattering. The traffic channel user data is supplied elsewhere in the receiving unit for further processing. If an emission identifying the transmission antenna branch has been added to the traffic channel, the identifier identifying the antenna branch or the signal shaping method is
5 detected from the received signal in detector 720 and it is led to checking unit 721 for verification of the antenna branch. The detector 720 may be implemented so that it is integrated with detector 713 in Figure 7a. The checking unit 721 compares the identifier identifying the antenna branch or the signal shaping method with the corresponding ones of the antenna branch
10 chosen earlier as transmission antenna branch in unit 701. If the identifiers or shaping methods are similar, it has been ensured that the antenna branch connected for transmission by transmitting unit 700 is the same as the optimum antenna branch chosen by receiving unit 701. If the identifiers or shaping methods are different from each other, checking unit 721 may
15 take the steps to be presented in the following, in accordance with the operating instructions established for the unit.

Firstly, checking unit 721 may notify decoder 712 through control route 732, that the decoder must use the channel estimate of another antenna branch for decoding the signal. Secondly, checking unit 721 may
20 through control route 731 control the transmitting side of receiving unit 701 to change the transmission settings in the transmission of the next antenna choice message. The signal including the next message may e.g. be controlled so that it is transmitted at a higher power or it may be processed with more powerful coding. Thirdly, checking unit 721 may make statistics of the
25 success of the antenna connection of transmitting unit 700 according to the antenna choice messages given by receiving unit. If the success of the antenna connection falls short of a pre-established threshold level, checking unit 721 may through route 731 control the transmitting side of receiving unit 701 to send to transmitting unit 700 a message that the antenna choice
30 functionality may/must be turned off. Having received this message, transmitting unit 700 will choose the antenna branch for transmission in some state-of-the-art manner.

The foregoing was a description of a preferred embodiment of the invention in a case where several transmission antenna branches are used.
35 In the following, the preferred embodiment of the invention will be described with reference to Figure 8 in a case where several antenna beams of a vari-

able beam antenna are used. Figure 8 shows antenna beams B1 - B3 of a variable beam antenna group located at base station BS. For the sake of clarity, the figure shows three antenna beams only, but when using a dynamic antenna, more such antenna beams can of course be formed. Figure 8 also shows the antenna beam B4 of an omnidirectional antenna. Each one of these antenna beams can be understood as corresponding to one transmission antenna branch of the example described above. In accordance with the present invention, base station BS transmits a common channel through each antenna beam B1 - B4. The signals to be transmitted through the different antenna beams have been shaped in the manner described above by an antenna beam specific signal shaping method. Mobile station MS receives all common channel signals, it compares the signals with one another and chooses the optimum transmission antenna beam. Mobile station MS notifies the base station of its antenna beam choice among the data to be transmitted. Based on the received antenna beam choice message, base station BS connects the user data to be transmitted to one antenna beam and shapes the user data to be transmitted with the signal shaping method of the transmission antenna beam which is to be used. Mobile station MS verifies the transmission antenna beam used for the transmission by this signal shaping method and, if required, it may take e.g. the steps presented above in case of a false antenna beam connection.

The invention was described above in the case of a connection between one base station BS and one mobile station MS. Figure 9 shows the first embodiment of the invention in a situation, where mobile station MS is simultaneously connected with more than one base station, but the functionality according to the invention is applied to one connection only. In the example shown in Figure 9, the functionality according to the invention is applied to the connection between mobile station MS and base station BS3, whereby for the connections between mobile station MS and base stations BS1 and BS2 some such transmission antenna route is used, which is chosen by some state-of-the-art method. In the situation shown in Figure 9, e.g. in a soft handover situation, base station BS3 thus through all its transmission antennas ANT1 and ANT2 transmits a common channel, whose signal has been shaped by a transmission antenna beam specific signal shaping method. Mobile station MS compares the received signals with one another and chooses the optimum transmission antenna branch for base station

BS3. Mobile station MS transmits to the base stations the antenna choice message among the data to be transmitted, but only base station BS3 interprets this data and uses the received and interpreted data for connecting the transmission antenna branch. Base station BS3 transmits user data intended for mobile station MS through the antenna branch which it has connected for the transmission. To this user data may be added an emission identifying the connected transmission antenna branch as described above, mobile station MS may verify the transmission antenna branch of base station BS3 by the identifier or signal shaping method which it has detected from the received signal and it may when required take e.g. the steps presented in connection with the description of Figure 7b. In a soft handover situation as the one shown in Figure 9, the mobile station MS may e.g. in the soft handover message notify the network of the connections of base station BS to which the functionality of the invention is to be applied .

Figure 10 shows the method in accordance with the invention in a case of a broadcast signal of several base stations. According to the invention, through each antenna of the base stations BS1 - BS3 shown as examples in Figure 10 such a broadcast signal is transmitted, which includes an individual emission identifying the transmission antenna branch. Mobile station MS receives these signals and based on them it chooses the optimum transmission antenna branch in the same manner as in the case of one base station. Mobile station MS sends a message of its antenna choice to the network. Based on the received antenna choice message, some transmission antenna ANT1 or ANT 2 of some base station BS1 - BS3 is connected for the communication. In a case of several antennas, the antenna choice message may have to be sent with several bits, so that each antenna will be identified in a manner different from the others. Hereby the bits of the antenna choice message may also be coded better than normally in order to ensure a safer data transmission. This example can be understood as describing a swift hard handover situation.

In another embodiment of the invention, an emission identifying the antenna branch is also formed in the broadcast signal by adding to the signal an identifier which is individual for each antenna branch. Hereby in a state-of-the-art manner such a common channel is transmitted through all antenna branches, to which, besides the broadcast data, is added an identifier which is individual for each antenna branch. Mobile station MS receives all these

signals and compares the signals with one another and chooses the optimum signal for reception hereafter. Mobile station MS makes known this antenna branch identifier of its choice to base station BS, which upon studying the message of the mobile station will transmit user data through that
5 antenna branch, which the base station BS understood to be the choice of mobile station MS. Through the connected transmission antenna branch user data is transmitted in accordance with the invention on the traffic channel and, when desired, the individual identifier of the antenna branch, which when received and interpreted by mobile station MS enables the mobile station to verify the used transmission antenna branch and when required to
10 take steps in case the transmission antenna branch was misinterpreted at the base station.

Corresponding to the above description of the preferred embodiment of the invention with reference to Figure 8, also a secondary embodiment of the invention may be implemented by using instead of transmission
15 antenna branches transmission antenna routes, e.g. transmission antenna beams. Also the soft handover situation presented above in connection with the description of Figure 9 or the functionality of the example shown in Figure 10 may be implemented by the secondary embodiment of the invention.

Figures 11a and 11b are flow charts of the method according to the invention. At point 101 the base station transmits a broadcast signal through all its transmission antenna routes, such as from all transmission antennas and/or antenna beams. Each broadcast signal includes an individual emission identifying the transmission antenna route, such as a signal shaping
20 method or a route identifier. At point 102 mobile station MS compares the received common channel signals, e.g. based on the signal level, the signal-to-interference ratio or the distance attenuation. Based on these signals, mobile station MS chooses the optimum transmission antenna route (point 103) and notifies the base station BS of its choice of antenna route (point
25 104). The antenna route choice message from mobile station MS to base station BS may be relayed by symbol puncturing in an uplink signal, such as a power control command, or by time multiplexing. The bits of the antenna route choice message may also be used to replace at least some of the power control bits to be transmitted in the uplink signal, however, preferably
30 in such a manner that power control will still succeed in a state-of-the-art manner. The bit or bits stating the choice of antenna route can also be effective-

tively coded against possible transmission errors. Based on the received antenna route choice message, base station BS connects one antenna route for the traffic channel transmission and through this antenna route it transmits a user data signal, which preferably includes an emission identifying the connected antenna route (point 105). At point 106 verification takes place in the mobile station of the connected transmission antenna route based on the emission identifying the antenna route which is detected from the received signal. At point 107 a check is made in mobile station MS, of whether the connected antenna route is in accordance with the chosen optimum antenna route. If the connected route is not in accordance with the choice, some of the alternative procedures A, B or C shown in Figure 11b will be carried out. In procedure A, the channel estimate of the connected antenna route is used for the decoding in the mobile station (point 108). In procedure B, the next antenna route choice is stated more effectively from mobile station MS to base station BS (point 109), e.g. at a higher transmission power or by coding the message with a better channel coding. In procedure C, statistics are made of antenna route choice implementation (point 110). At point 111 a check is made of whether the antenna route choice has been successfully implemented a sufficient number of times. If the choice has failed too often in relation to an established threshold value, a message of this matter is transmitted from mobile station MS to base station BS (point 112). Mobile station MS may command/request the base station to turn off the functionality according to the invention or it may allow the base station hereafter freely to choose the antenna route to be connected.

Figure 12 illustrates the functionality of a third embodiment of the invention. In the third embodiment of the invention, mobile station MS is connected with more than one base station at the same time, e.g. in a soft handover situation, and it chooses the transmission antenna branches of these base stations in the manner according to the invention. In the example shown in Figure 12, mobile station MS is connected with base stations BS1 - BS3 at the same time. In each one of these base stations there are two transmission antennas ANT1 and ANT2. In accordance with the above description, each base station BS1 - BS3 transmits a common channel through all its transmission antennas ANT1 - ANT2. The signals to be transmitted through the different antenna branches include an emission identifying the transmission antenna branch, e.g. in the manner described above a signal

shaping method or an antenna branch identifier, which differs from the emission identifying the other antenna of the same base station. The first antennas ANT1 and the second antennas ANT2 of the different base stations preferably have corresponding emissions identifying the antenna. Mobile station MS receives all common channel signals, in the case shown in Figure 12 six common channels, and compares the received signal formed jointly by the antennas ANT1 of all base stations with the signal formed jointly by the antennas ANT2 of all base stations, e.g. the formed signal level, the signal-to-interference ratio or the distance attenuation. Mobile station MS chooses the optimum transmission antenna group ANT1 or ANT2 and transmits to the base stations an antenna choice message among the data to be relayed to the base stations. The base stations receive the message and according to their interpretation they connect one of their transmission antenna branches as the antenna branch to be transmitted. User data may be shaped on the traffic channel in such a way that at the same time an emission identifying the antenna branch to be used for the transmission is relayed to the mobile station, e.g. the signal shaping method or the antenna branch identifier. From this emission, the mobile station MS verifies the transmission antenna branch used by each base station. If the connection of the transmission antenna branch was not successful at all base stations in accordance with the message of the mobile station, the mobile station may take e.g. the steps presented in connection with the description of Figure 7b.

The choice and connection of antenna route according to the invention may be carried out in time at standard intervals, e.g. every fourth transmission time slot, or at any random moment.

In a fourth embodiment of the invention, the functionality according to the invention can be turned off for the time of a soft handover situation. If the choice of transmission antenna route according to the invention is performed at standard intervals of time, this may be implemented e.g. by a message from mobile station MS to the network in a soft handover message. Mobile station MS may make known in this message, that no antenna route choice message in accordance with the invention will be transmitted for the time being. When the soft handover situation is over, mobile station MS may send to the network a message that the choice of antenna route continues or it may simply send the antenna route choice message to the base station among the data which is to be sent to the base station. If the choice of

transmission antenna route is performed at a random moment, the functionality according to the invention can be most easily turned off for the time of a soft handover situation in such a way that mobile station MS does not transmit any antenna route choice messages during the soft handover situation, but only after this situation.

In a fifth embodiment of the invention, the base station transmits essentially at the same time through its several transmission antenna routes to mobile station MS on the traffic channel an identifier identifying the individual transmission antenna route, e.g. in the case shown in Figure 3a through transmission antennas ANT1 - ANT3. Mobile station MS receives the traffic channel signal of all transmission antenna routes and from these received signals it determines which one is best, e.g. based on the signal level, the SIR (Signal to Interference Ratio) or the distance attenuation. Mobile station MS notifies base station BS of the best transmission antenna route of its choice with the aid of an identifier which it has perceived in the traffic channel signal of the concerned transmission antenna route. With the aid of bit sequences of the identifier it is also possible to improve the comparison of signals of the transmission antenna routes in the receiving unit. Using these it is e.g. possible to calculate the channel power or channel estimates for the different transmission antenna routes. The transmission of user data to mobile station MS is continued on the basis of the antenna choice information received by the base station through one transmission antenna route only, in the example shown in Figure 3b through antenna ANT2. The choice of transmission antenna route in the receiving unit is preferably made from the traffic channel signals of one time slot for the user data transmission of the following time slot. Thus, on the traffic channel of each transmission antenna route an identifier is transmitted for the choice of antenna route, but user data is transmitted only through one transmission antenna route. The transmission antenna routes are e.g. transmission antenna branches or transmission antenna beams.

It is advantageous that in the fifth embodiment of the invention base station BS also among the user data transmits on the traffic channel an identifier identifying the transmission antenna route for use in the transmission or that it shapes the user data to be transmitted on the traffic channel in accordance with the signal shaping method of the transmission antenna route to be used for the transmission, whereby mobile station MS will be able

to verify the transmission antenna route to be used for the transmission, as has been presented above in connection with the description of the other embodiments.

Transmission antenna route specific signal shaping methods are
5 e.g. the different hash codes presented in connection with the other embodiments, the same hash code with a different symbol pattern, a different frequency offset, a different channel coding and/or a different number of hash codes in parallel. The signal shaping method to be established for different transmission antenna routes is preferably orthogonal in comparison
10 with the signal shaping methods of the other antenna routes. The individual signal shaping method of the transmission antenna route or the identifier added to user data on the traffic channel may be the same as the identifier used for the choice of antenna on the traffic channel or some signal shaping method or identifier connected thereto, so that the mobile station will identify
15 the connected transmission antenna route and will be able to compare it with the individual identifier of the transmission antenna route of its choice. The individual identifier is added to the traffic channel e.g. by symbol puncturing, time multiplexing or code multiplexing. The identifier to be used in the choice of a transmission antenna route may be transmitted on traffic channels
20 through different transmission antenna routes at the same time and/or with time division. Orthogonal symbol patterns or hash codes are preferably used in simultaneous transmission. In time division transmission, the bit sequence of the identifier may be the same as such, when it is possible owing to the time division to interpret the identifier individually for the different antenna
25 routes. For example, in the case of two antenna routes, it is possible through the first transmission antenna route on the traffic channel to transmit identifier P1 P2 - - and through the second transmission antenna route the identifier - - P1 P2, wherein '-' means that there is no transmission through the route. To form an individual identifier for the transmission antenna route one
30 may also use any combination of the methods mentioned above.

In the fifth embodiment of the invention, the structure of downlink traffic channels is similar to the traffic channels of the example shown in Figure 6. According to the invention, the traffic channels include a user data item and the antenna route's symbol pattern item, which is the symbol pattern
35 of the antenna route connected for use by each subscriber connection. The symbol pattern may also be used for shaping the bits of the user data

item. The symbol pattern identifying the antenna route may be located in a suitable place on the traffic channel. Correspondingly, the other signal shaping methods mentioned above as examples, the data bits shaped by them as well as the identifiers identifying the antenna route are located in the traffic channels shown in Figure 6. If such an identifier is also used on the traffic channel which verifies the antenna route connected for transmission of user data, the symbol pattern item may be split up, whereby e.g. the first two bits indicate the identifier for use in the choice of antenna route while the last two bits indicate the identifier for use in the verification of the connected antenna route. The identifier for use in the choice of antenna route may be formed e.g. by treating some established standard data with an individual signal shaping method.

In addition to that which has been described above, the fifth embodiment of the invention may also be combined with the transmission of a broadcast signal provided with an individual emission from all transmission antenna branches as described earlier in connection with the preferred embodiment of the invention. Hereby the choice of transmission antenna route in the mobile station takes place based both on the traffic channel signal and the broadcast signal.

The arrangement according to the fifth embodiment of the invention described above includes instead of the broadcasting means identifying means for transmitting an individual emission on the traffic channel through each transmission antenna route, so that the emission will identify the transmission antenna route. In other respects the arrangement of the fifth embodiment of the invention is similar to the arrangement of the other embodiments described above.

It is an advantage of the fifth embodiment of the invention that the emission, which identifies the transmission antenna route and which is to be transmitted through all transmission antenna routes, can be transmitted on the traffic channel controlled by power control. Hereby the comparison of traffic channel signals for the choice of antenna becomes more reliable, when the variation in received power of these signals is less than without power control, and, in addition, the interference caused elsewhere in the network remains small. The mobile station may in a state-of-the-art manner transmit power control commands to the base station in order to control the transmission power of the traffic channel. The need for power control is de-

terminated in a state-of-the-art manner from the previous slot transmitted from the base station. Power control is connection specific. Relative power difference information on the identifier part of different traffic channel transmissions is sufficient for a comparison of traffic channel signals in accordance with the invention. The traffic channel identifiers can also be transmitted with the same power through different transmission antenna routes.

The fifth embodiment of the invention is especially advantageous in the case of a few receiving units, e.g. a mobile station MS. The identifier for use in the choice of transmission antenna route on the traffic channel may be transmitted e.g. only to receivers applying the method according to the invention as a point-to-point transmission. For the transmission of user data, an optimum transmission antenna route is connected individually for each receiving unit.

Although in the above fifth embodiment of the invention the application of the invention was presented in connection with a traffic channel, the invention can be used with the aid of any connection specific point-to-point channel. Thus, the traffic channel described above as an example means any connection specific channel.

The present invention may be applied together with any mobile communications system. The most advantageous application of the invention is the CDMA system, because multi-path channel estimates are constantly available directly in a CDMA receiver, and they need not be counted separately. The invention is especially advantageous in connection with a frequency division duplex transmission FDD.

The drawings and the related explanation are only intended to illustrate the inventive idea. As regards details, the transmission antenna diversity according to the invention may vary within the scope of the claims. Although the invention was described above mainly in connection with the choice of a downlink direction transmission antenna route transmitting from a base station to a mobile station, the invention may also be used for choosing an uplink direction transmission antenna route where the transmission is in the other direction, that is, from terminal equipment to base station, if the terminal equipment uses at least two transmission antennas and/or transmission antenna beams located at a sufficient distance from each other. The transmission antenna diversity according to the invention is suitable for implementation with transmission antenna routes of different kinds, such as

transmission antenna branches and/or transmission antenna beams, even though the invention was described above mainly in connection with transmission antenna branches.

1. Method for implementing transmission antenna diversity in a mobile communications system, which includes at least two receiving units (MS, 701) and at least one transmitting unit (BS, 700), wherein there are at least two transmission antenna routes (44, 45, 46; B1, B2, B3, B4), in which mobile communications system the receiving unit (MS, 701) and the transmitting unit (BS, 700) are in data transmission connection with one another over a radio path, in which method

broadcast is transmitted through each transmission antenna route (44, 45, 46; B1, B2, B3, B4) of the transmitting unit (BS, 700),

the optimum transmission antenna route is chosen with the aid of broadcast signals in the receiving unit (MS, 701) ,

the chosen transmission antenna route is made known to the transmitting unit (BS, 700),

user data is transmitted through the transmission antenna route connected for use from the transmitting unit (BS, 700),

characterised in that in the method

in the transmitting unit (BS, 700) data is produced in the broadcast signal of each transmission antenna route which individualises the transmission antenna route (44, 45, 46; B1, B2, B3, B4),

an identification is made in the receiving unit based on the data included in the broadcast signal to find out from which transmission antenna route each broadcast signal was transmitted,

based on the received antenna route choice message, the transmission antenna route is connected individually to each receiving unit.

2. Method as defined in claim 1, characterized in that to identify the transmission antenna route, an individual emission of the connected transmission antenna route is added to the user data signal to be transmitted.

3. Method as defined in claim 2, characterized in that the connection of the transmission antenna route is checked in the receiving unit (MS, 701) based on the individual emission added to the user data signal.

the individual emission of the transmission antenna route connected for transmission is compared with the signal shaping method of the
5 chosen optimum transmission antenna route.

6. Method as defined in claim 5, characterized in that in the message to the transmitting unit (BS, 700) the transmitting unit is controlled to choose a pre-established transmission antenna route.

8. Method as defined in claim 7, c h a r a c t e r i z e d in that the
20 next signal including an antenna route choice message is transmitted with a
higher transmission power.

10. Method as defined in claim 4, c h a r a c t e r i z e d in that the
25 channel estimate of the chosen optimum transmission antenna route is used
for breaking up the received user data, and

30 11. Method as defined in claim 1 or 2, characterized in that the transmission of each transmission antenna route (44, 45, 46; B1, B2, B3, B4) is shaped by an individual signal shaping method, which is an individual frequency offset.

12. Method as defined in claim 1 or 2, characterized in that
35 the transmission of each transmission antenna route (44, 45, 46, B1, B2, B3,

B4) is shaped by an individual signal shaping method, which is an individual hash code symbol pattern.

13. Method as defined in claim 1 or 2, characterized in that the transmission of each transmission antenna route (44, 45, 46; B1, B2, B3, B4) is shaped by an individual signal shaping method, which is an individual hash code.

14. Method as defined in claim 1 or 2, characterized in that the transmission of each transmission antenna route (44, 45, 46; B1, B2, B3, B4) is shaped by an individual signal shaping method, wherein on different antenna routes the signal is modulated by a different number of hash codes in parallel.

15. Method as defined in claim 1 or 2, characterized in that the transmission of each transmission antenna route (44, 45, 46; B1, B2, B3, B4) is shaped by an individual signal shaping method, which is an individual channel coding.

16. Method as defined in claim 1 or 2, characterized in that for each transmission antenna route (44, 45, 46; B1, B2, B3, B4) an individual signal shaping method is established, which is orthogonal in relation to the signal shaping method of the other transmission antenna routes.

17. Method as defined in claim 1, characterized in that broadcast is transmitted through each transmission antenna route (44, 45, 46; B1, B2, B3, B4) of the transmitting unit (BS, 700), so that the broadcast signals of the different transmission antenna routes include at least one information part which is the same.

18. Method as defined in claim 17, characterized in that broadcast is transmitted through each transmission antenna route (44, 45, 46; B1, B2, B3, B4) of the transmitting unit (BS, 700), so that the information part is the same in the broadcast signal of the different transmission antenna routes.

19. Method as defined in claim 1, characterized in that broadcast is transmitted through each transmission antenna route (44, 45, 46; B1, B2, B3, B4) of the transmitting unit (BS, 700), so that the broadcast signal is divided between the different transmission antenna routes.

20. Method as defined in claim 1 in a mobile communications system, wherein there are at least two receiving units (MS) and at least two

5

10

15

15

20

20

30

independently of the transmission antenna branches connected to the other receiving units.

24. Method as defined in claim 23, characterized in that the chosen transmission antenna branch is identified with the aid of the signal shaping method which is individual for the transmission antenna branch,

for identification of the transmission antenna branch, an emission individual for the transmission antenna branch connected for transmission is added to the user data signal to be transmitted, and

based on this emission, the connection of the transmission antenna branch is checked in the receiving unit (MS, 701).

25. Method as defined in claim 1 in a mobile communications system, where in the transmitting unit (BS, 700) there are at least two transmission antenna beams (B1, B2, B3, B4), in which method

broadcast is transmitted from each transmission antenna beam (B1, B2, B3, B4) of the transmitting unit (BS, 700)

based on the broadcast signals, the optimum transmission antenna beam is chosen in the receiving unit (MS, 701),

the chosen transmission antenna beam is made known to the transmitting unit (BS, 700),

user data is transmitted through the transmission antenna beam connected for use from the transmitting unit (BS, 700),

characterised in that in the method

in the transmitting unit (BS, 700) data individualising the transmission antenna beam (B1, B2, B3, B4) is produced in the broadcast signal of each transmission antenna beam,

the data individualising the transmission antenna beam and included in the broadcast signal is identified in the receiving unit (MS, 701),

based on the received antenna choice message, a transmission antenna beam is connected to each receiving unit independently of the transmission antenna beams connected to the other receiving units.

26. Method as defined in claim 25, characterized in that

the chosen transmission antenna beam is identified in the antenna choice message with the aid of the signal shaping method which is individual

for the concerned transmission antenna beam,

for identification of the transmission antenna beam, an emission individual for the transmission antenna beam connected for transmission is added to the user data signal to be transmitted, and

based on this emission, the connection of the transmission antenna
5 beam is checked in the receiving unit (MS, 701).

27. Method for implementing transmission antenna diversity in a mobile communications system, wherein a receiving unit (MS, 701) and at least one transmitting unit (BS, 700) are in data transmission connection with each other over a radio path, in which transmitting unit (BS, 700) there are at least two transmission antenna routes (44, 45, 46; B1, B2, B3, B4), in which method

broadcast is transmitted through each transmission antenna route (44, 45, 46; B1, B2, B3, B4) of the transmitting unit (BS, 700), so that the broadcast signals of the different transmission antenna routes include at least the one same information part ,

the received broadcast signals of each transmission antenna route are estimated in the receiving unit (MS, 701),

based on the broadcast signals, the optimum transmission antenna route is chosen in the receiving unit (MS, 701),

the chosen transmission antenna route is made known to the transmitting unit (BS, 700),

based on the received antenna route choice message, user data is transmitted through the transmission antenna route connected for use from the transmitting unit (BS, 700),

25 characterised in that in the method

at least one individual signal shaping method is established for each transmission antenna route (44, 45, 46; B1, B2, B3, B4)

the broadcast signal of each transmission antenna route is shaped in the transmitting unit (BS, 700) by a signal shaping method which is individual for each transmission antenna route (44, 45, 46; B1, B2, B3, B4),

the chosen transmission antenna route is identified in the antenna route choice message with the aid of the signal shaping method individual for the concerned transmission antenna route, and

to identify the transmission antenna route, an emission individual for the transmission antenna route connected for use is added to the user data signal to be transmitted.

28. Method for implementing transmission antenna diversity in a mobile communications system, which includes at least two receiving units (MS) and at least one transmitting unit (BS), wherein there are at least two transmission antenna routes (44, 45, 46; B1, B2, B3, B4), in which mobile communications system the receiving unit (MS) and the transmitting unit (BS) are in data transmission connection with each other over a radio path, in which method

broadcast is transmitted through each transmission antenna route (44, 45, 46; B1, B2, B3, B4) of the transmitting unit (BS) together with an identifier identifying each antenna route,

- the received broadcast signals of each antenna route are estimated in the receiving unit (MS),

the optimum transmission antenna route is chosen in the receiving unit (MS) with the aid of the broadcast signals,

the chosen transmission antenna route is made known to the transmitting unit (BS),

- user data is transmitted through the transmission antenna route connected for use from the transmitting unit (BS),

characterised in that in the method

based on the received antenna route choice message, a transmission antenna route is connected individually for each receiving unit.

29. Method as defined in claim 28, characterized in that to identify the transmission antenna route, an identifier identifying the transmission antenna route connected for transmission is transmitted among the user data.

30. Method as defined in claim 29, characterized in that in the receiving unit (MS) the connection of the transmission antenna route is checked based on the identifier to be transmitted among the user data.

31. Method as defined in claim 30, characterized in that in order to check the connection of the transmission antenna route

32. Method as defined in claim 31, characterized in that
5 statistics are made on the matching of the connected transmission
antenna route with the chosen optimum transmission antenna route, and
the transmitting unit (BS) is notified, when in terms of quantity the
matching falls short of a pre-established threshold value.

34. Method as defined in claim 31, characterized in that in the transmission of the next antenna route choice message the transmission settings of the signal are changed, if the connection of the transmission antenna route is different from the chosen optimum transmission antenna route.

20 36. Method as defined in claim 34 or 35, c h a r a c t e r i z e d in
that the next antenna route choice message is coded with better channel
coding.

the connected transmission antenna route is established as the chosen optimum transmission antenna route, when these routes are different from each other.

39. Method as defined in claim 29, characterized in that an identifier identifying the transmission antenna route is added to the user data in every transmission time slot.

41. Method as defined in claim 28 in a mobile communications system, wherein the receiving unit (MS) and at least two transmitting units (BS1, BS2, BS3) are in a simultaneous data transmission connection with each other over a radio path, characterised in that based on the broadcast signals of the transmitting units (BS1, BS2, BS3) a choice is made in the receiving unit (MS) of the optimum combination of transmission antenna routes, which includes one transmission antenna route of each transmitting unit (BS1, BS2, BS3).

15 units (BS1, BS2, BS3), characterised in that based on the broadcast signals of the transmitting units (BS1, BS2, BS3) a choice of the optimum transmission antenna route is made in the unit (MS).

one transmitting unit (BS) are in data transmission connection with each other over a radio path, in which transmitting unit there are at least two transmission antenna routes (44, 45, 46; B1, B2, B3, B4), in which method broadcast is transmitted through each transmission antenna route (44, 45, 46; B1, B2, B3, B4) of the transmitting unit (BS),

25 the received broadcast signals of each antenna route are estimated
in the receiving unit (MS),

based on the broadcast signals, the optimum transmission antenna route is chosen in the receiving unit (MS),

the chosen transmission antenna route is made known to the
30 transmitting unit (BS),

based on the received antenna route choice message, user data is transmitted through the transmission antenna route connected for use from the transmitting unit (BS),

characterised in that in the method

44. Method for implementing transmission antenna diversity in a mobile communications system, which includes at least two receiving units (MS, 701) and at least one transmitting unit (BS, 700), wherein there are at least two transmission antenna routes (44, 45, 46; B1, B2, B3, B4), in which mobile communications system the receiving unit (MS, 701) and the transmitting unit (BS, 700) are in a data transmission connection with each other over a radio path, in which method

user data is transmitted through the transmission antenna route
connected for use from the transmitting unit (BS, 700) on a connection spe-
cific channel.

through each transmission antenna route such an individual emission is transmitted on a connection specific channel which identifies each transmission antenna route,

based on the signals of the transmission antenna routes, the optimum transmission antenna route is chosen in the receiving unit (MS, 701), and

45. Method as defined in claim 44, c h a r a c t e r i z e d in that to identify the transmission antenna route, an identifier individual for the transmission antenna route connected for use is added to the user data signal.

47. Method as defined in claim 44 or 45, characterized in
35 that the transmission of the connection specific channel of each transmission

antenna route (44, 45, 46; B1, B2, B3, B4) is shaped by an individual signal shaping method, which is an individual frequency offset.

48. Method as defined in claim 44 or 45, characterized in that the transmission of the connection specific channel of each transmission antenna route (44, 45, 46; B1, B2, B3, B4) is shaped by an individual signal shaping method, which is an individual hash code symbol pattern.

49. Method as defined in claim 44 or 45, characterized in that the transmission of the connection specific channel of each transmission antenna route (44, 45, 46; B1, B2, B3, B4) is shaped by an individual signal shaping method, which is an individual hash code.

50. Method as defined in claim 44 or 45, characterized in that the transmission of the connection specific channel of each transmission antenna route (44, 45, 46; B1, B2, B3, B4) is shaped by an individual signal shaping method, wherein on the different antenna routes the signal is modulated by a different number of hash codes in parallel.

51. Method as defined in claim 44 or 45, characterized in that the transmission of the connection specific channel of each transmission antenna route (44, 45, 46; B1, B2, B3, B4) is shaped by an individual signal shaping method, which is an individual channel coding.

52. Method as defined in claim 44 or 45, characterized in that for each transmission antenna route (44, 45, 46; B1, B2, B3, B4) an individual signal shaping method is established, which is orthogonal in relation to the signal shaping method of the other transmission antenna routes.

53. Method as defined in claim 44 or 45, characterized in that on the connection specific channel an individual identifier is transmitted which identifies the transmission antenna route.

54. Method as defined in claim 44 or 45, wherein broadcast is transmitted through each transmission antenna route (44, 45, 46; B1, B2, B3, B4) of the transmitting unit (BS, 700), the received broadcast signals of each transmission antenna route are estimated in the receiving unit (MS, 701),

characterised in that in the method based on the signals of the connection specific channel and the broadcast signals of each transmission antenna route, the optimum transmission antenna route is chosen in the receiving unit (MS, 701).

55. Arrangement for implementing transmission antenna diversity in a mobile communications system, which includes at least two receiving units (MS, 701) and at least one transmitting unit (BS, 700), wherein there are at least two transmission antenna routes (44, 45, 46; B1, B2, B3, B4), in which mobile communications system the receiving unit (MS, 701) and the transmitting unit (BS, 700) are in a data transmission connection with each other over a radio path, characterised in that the arrangement includes

in the transmitting unit (BS, 700):

broadcasting means (43, 47) for transmitting a broadcast signal through each transmission antenna route, so that information individualising the transmission antenna route is produced in the signals to be transmitted, switching means (54) for connecting the individual transmission antenna route to the transmission of user data, and

in the receiving unit (MS, 701):

choosing means (713, 714) for choosing an optimum transmission antenna route based on the received broadcast signals and for notifying the transmitting unit of the choice.

56. Arrangement as defined in claim 55, characterised in that it also includes in the transmitting unit (BS, 700):

communication means (53) for shaping the user data to be transmitted in such a way that it identifies the connected transmission antenna route.

57. Arrangement as defined in claim 56, characterised in that it also includes in the receiving unit (MS, 701)

verification means (721) for verifying the transmission antenna route of the connected user data.

58. Arrangement as defined in claim 56, characterised in that it also includes in the transmitting unit (BS, 700)

a control (59) responding to the message of the choosing means of the receiving unit to control the switching means (54) and the communication means (53).

59. Arrangement for implementation of transmission antenna diversity, which arrangement includes a receiving unit (MS, 701) and at least one transmitting unit (BS, 700), which are in a data transmission connection with

in the transmitting unit (BS, 700):

communication means (54, 53) for connecting the transmission route to the transmission of user data and for shaping the user data transmitted in such a way that it identifies the connected transmission route, and

choosing means (713, 714) for choosing the optimum transmission route based on the received broadcast signals and for notifying the receiving unit of the choice.

in the transmitting unit (BS, 700):

switching means (54) for connecting the individual transmission route to the transmission of user data, and

choosing means (713, 714) for choosing the optimum transmission antenna route based on the received signals of each transmission antenna route and for notifying the transmitting unit of the choice.

61. Arrangement as defined in claim 60, characterised in that it also includes in the transmitting unit (BS, 700):

communication means (53) for shaping the user data to be transmitted in such a way that it will identify the connected transmission antenna route.

62. Arrangement as defined in claim 61, characterised in that it also includes in the receiving unit (MS, 701)

verification means (721) for verification of the transmission antenna route of the connected user data.

63. Arrangement as defined in claim 61, characterised in that it also includes in the transmitting unit (BS, 700)

a control (59) responding to the message of the choosing means of the receiving unit to control the switching means (54) and the communication means (53).

64. Traffic channel structure for relaying data from a transmitting unit to a receiving unit over a radio path, which structure includes data to be transmitted, characterised in that the data included in the traffic channel structure has been shaped by a transmission antenna route specific signal shaping method of the transmitting unit.

65. Traffic channel structure for relaying data from a transmitting unit to a receiving unit over a radio path, which structure includes data to be transmitted, characterised in that the traffic channel structure also includes a transmission antenna route specific identifier of the transmitting unit.

ABSTRACT

TRANSMISSION ANTENNA DIVERSITY

In mobile communications systems transmission antenna diversity is used e.g. to compensate for fading caused to the signal on the radio path. It is known to make the choice of transmission antenna jointly for all subscriber connections, but it is not hereby possible to offer the optimum transmission antenna to simultaneous connections. The present invention aims at a method for implementing transmission antenna diversity on a data transmission connection, which is set up between a transmitting unit (BS), wherein there are several transmission antenna routes (ANT1, ANT2, ANT3), and a receiving unit (MS1, MS2). In the method, a broadcast signal is transmitted through all transmission antenna routes (ANT1, ANT2, ANT3) of the transmitting unit, with the aid of these signals a choice is made in the receiving unit (MS1, MS2) of the optimum transmission antenna route connected for use. According to the invention, the method is characterised in that the broadcast signal of each transmission antenna route is shaped by an individual signal shaping method which is different from the others and a transmission antenna route is connected for use based on the received antenna choice message, individually for each receiving unit.

Declaration and Power of Attorney Patent Application (Design or Utility)

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name,

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled:
TRANSMISSION ANTENNA DIVERSITY

the specification of which

- ☐ is referred to by Altera reference number on a separate document
☒ is attached hereto
☐ was filed on 13 September 2000 as application serial no. _____
 and or PCT International Application number _____ and was amended on _____ (if
 applicable).

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose to the U.S. Patent and Trademark Office all information know to me to be material to patentability as defined in 37 C.F.R. §1.56.

I hereby claim foreign priority benefits under 35 U.S.C. § 119(a)-(d) or 35 U.S.C. § 365(b) of any foreign application(s) for patent or inventor's certificate, or 35 U.S.C. § 365(a) of any PCT International application which designated at least one country other than the United States, listed below and have also identified below any foreign application for patent or inventor's certificate of PCT International application having a filing date before that of the application on which priority is claimed.

Prior Foreign Application(s)		
Number 980915	Country Finland	Day/Month/Year Filed 24 April 1998
Number 981377	Country Finland	Day/Month/Year Filed 12 June 1998
Number	Country	Day/Month/Year Filed

[illegible]

I hereby claim the benefit under 35 U.S.C. §120 of any United States application(s), or under 35 U.S.C. §365(c) of any PCT International application designating the United States, listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States or PCT International application in the manner provided by the first paragraph of 35 U.S.C. §112, I acknowledge the duty to disclose to the U.S. Patent and Trademark Office all information known to me to be material to patentability as defined in 37 C.F.R. §1.56 which became available between the filing date of the prior application and the national or PCT International filing date of this application:

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements are made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under 18 U.S.C. § 1001 and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

Power of Attorney

As a named inventor, I hereby appoint the following attorney(s) and/or agent(s) to prosecute this application and transact all business in the Patent and Trademark Office connected therewith.

Steven R. Funk Reg. No. 37,830
David W. Lynch Reg. No. 36,204
Karen D. McDaniel Reg. No. 37,674

Mark A. Hollingsworth Reg. No. 38,491
Michael B. Lasky Reg. No. 29,555
Iain A. McIntyre Reg. No. 40,337

I hereby authorize them or others whom they may appoint to act and rely on instructions from and communicate directly with the person/organization who/which first sends this case to them and by whom/which I hereby declare that I have consented after full disclosure to be represented unless/until I instruct Altera Law Group, LLC otherwise.

Please direct all correspondence in this case to Altera Law Group, LLC at the address indicated below:
